SECTION VII

DISINFECTION AND STERILIZATION
ANTISEPTICS AND DISINFECTANTS

ANTISEPTICS

Antiseptics are designed to be used for reducing or destroying micro-organisms on the skin or mucous membranes without damaging these tissues.

Uses of Antiseptics

Antiseptics are used for:

- Skin, cervical, or vaginal preparation before a clinical procedure
- Surgical scrub
- Handwashing in high-risk situations, such as before an invasive procedure or contact with a patient at high-risk of infection, (e.g. a newborn or immuno-suppressed patient) (see Table 7).

Antiseptics are not meant to be used on inanimate objects, such as instruments and surfaces. They usually do not have the same killing power as chemicals used for disinfection of inanimate objects.

| Hexachlorophene (e.g. pHisoHex) | • Not recommended for use in surgical scrub or patient preparation due to its limited antimicrobial effectiveness. | • Good persistent effect with repeated use.  
• Remains effective at least 6 hours after application. | • Potentially toxic to the nervous system | • Routine use of hexachlorophene is not recommended because of neurotoxicity and potential absorption through the skin.  
• Poor effectiveness against most microorganisms. |
DISINFECTANTS

Purpose of Disinfectants

Disinfectants are chemicals used to kill micro-organisms on infected instruments. Disinfectants are not meant to be used on the skin or mucous membranes.

Types of Disinfectants

There are three types of disinfectants (see Table 8):

1. **High-level disinfectants**
   - Kill bacteria, viruses, fungi, *Mycobacterium tuberculosis* and some, but not necessarily all bacterial endospores. Some high-level disinfectants are also chemical sterilants and, given sufficient time, will destroy bacterial endospores.
   - Are used for processing instruments and other items that are semi-critical.

2. **Intermediate-level disinfectants**
   - Kill mycobacteria, most viruses, and bacteria.
   - Recommended for use on blood and other potentially infectious materials.
   - Small, non-lipid viruses, (e.g. enteroviruses) may be resistant.
   - Used for some non-critical items, or devices, or environmental surfaces.

3. **Low-level disinfectants**
   - Kill some bacteria and some viruses and fungi, but do not kill tuberculosis-causing micro-organisms and bacterial endospores.
   - Are used for cleaning surfaces, such as floors and counter tops.
   - They should not be used for processing instruments and other items.

<th>Uses</th>
<th>Advantages</th>
<th>Disadvantages</th>
<th>Comments</th>
</tr>
</thead>
</table>
| Iodophors Iodine-based complexes, e.g. Povidone-iodine | **Intermediate-level disinfectant** for some equipment (hydrotherapy tanks, thermometers)  
**Low-level disinfectant** for hard surfaces and equipment that does not touch mucous membranes (e.g. IV poles, wheelchairs, beds, call bells). | • Rapid action  
• Relatively free of toxicity and irritancy. | • Antiseptic iodophors are not suitable for use as hard surface disinfectant.  
• Corrosive to metal unless combined with inhibitors.  
• Disinfectant may burn tissue.  
• Inactivated by organic materials.  
• May stain fabrics and synthetic materials. | • Povidone-iodine complex is used as a skin antiseptic and pre-operation scrub. |
| Peracetic acid | **High-level disinfectant** or sterilant for heat sensitive equipment.  
Higher concentrations used as chemisterilants in specially designed machines for decontamination of heat sensitive medical devices. | • Innocuous decomposition (water, oxygen, acetic acid, hydrogen peroxide)  
• Rapid action at low temperature  
• Active in presence of organic materials. | • Can be corrosive  
• Unstable when diluted. | |
| Phenolics | **Low-/intermediate-level disinfectant:**  
Clean floors, walls and furnishings.  
Clean hard surfaces and equipment that does not touch mucous membranes (e.g. IV poles, wheelchairs, beds, call bells). | • Leaves residual film on environmental surfaces.  
Commercially available with added detergents to provide one-step cleaning and disinfecting. | • Do not use in nurseries.  
• Not recommended for use on food contact surfaces.  
• May be absorbed through skin or by rubber.  
• Some synthetic flooring may become sticky with repetitive use. | • Relatively broad spectrum.  
• Suitable for low-level environmental disinfection only.  
• Useful against mycobacteria but cannot be used if HIV or HBV are present. |
| Quaternary ammonium compounds | **Low-level disinfectant:**  
Clean floors, wall and furnishings  
Clean blood spills. | • Generally non-irritating to hands.  
Usually have detergent properties. | • DO NOT use to disinfect instruments.  
• Non-corrosive.  
• Limited use as disinfectant because of narrow microbicidal spectrum. | • Contamination of weak solution with Gram-negative bacteria can be a hazard. |

The Effectiveness of Disinfectants

To be effective, the chosen disinfectant must:

1. Kill or inhibit the growth of the undesirable micro-organisms.

2. Not be harmful to the instrument/equipment on which it is used.

3. Be used only on clean, rinsed and dried instruments/equipment. Protein material, detergent and soap will inhibit some disinfectants.

4. Be used in the proper concentration.

5. Be used within the stipulated lifetime after dilution.

Factors Affecting Disinfection

1. Nature of the item to be disinfected

   - The rougher the surface, the longer the contact time required for disinfection (crevices, hinges, lumen).

2. Number of micro-organisms present

   - The number of micro-organisms present will lengthen the time for effective disinfection to take place. In general, higher bioburden requires more time for disinfection.

3. Resistance of micro-organisms

   - Some micro-organisms are more resistant to disinfection than others. The generally accepted order from the most resistant to the least resistant is: bacterial spores, mycobacteria, hydrophilic viruses, fungi, vegetative bacteria, lipid viruses.

   - Disinfecting a spill with a small concentration of bacterial spores will require longer disinfection time than a large concentration of lipid viruses.

   - Certain organisms, which flourish in a health care facility environment (such as *Pseudomonas aeruginosa* and other antibiotic-resistant micro-organisms), have an inherent resistance to certain disinfectants, while other organisms may develop resistance as a result of environmental selection.
4. **Type and concentration of disinfectant used**

- Resistance of micro-organisms depends on the type of disinfectant used. A particular micro-organism may be more resistant to one type of disinfectant than another. For instance, alcohol (isopropyl or ethyl) is effective against vegetative bacteria and most lipophilic viruses, but is not effective against bacterial spores or most hydrophilic viruses.

- Many disinfectants are broad spectrum; that is, effective against all or most forms of microbial life.

- Some broad spectrum disinfectants include glutaraldehyde, sodium hypochlorite (bleach), and hydrogen peroxide.

- Non-broad spectrum disinfectants include phenolics and quaternary ammonium compounds.

- Alcohols lie somewhere in between these two.

5. **Presence of organic material**

- The presence of organic soiling matter will compromise disinfection.

- Blood, blood products, body fluids, and faeces contain significant amounts of proteins, and protein will bind and inactivate some disinfectants or slow their action. Therefore, in the presence of large amounts of protein, a higher concentration of disinfectant and longer contact time will be necessary to achieve maximal disinfection.

6. **Duration of exposure and temperature**

- Duration of exposure and temperature influences the disinfection process. The longer the duration of exposure, the higher the degree of disinfection achieved.

- Some disinfectants require a longer contact time to achieve killing, and some microorganisms need longer exposures to be killed.

- Higher temperatures increase the killing power of most disinfectants, whereas lower temperatures may slow the killing power of most disinfectants.
Choice of Disinfection Methods

1. When compatible with other requirements, disinfectants used should be bacteriocidal rather than bacteriostatic; active against a wide range of micro-organisms and should not be readily inactivated.

2. Disinfectants are used under a variety of conditions, therefore the one chosen should be considered in terms of acceptability, availability, cost, as well as antibacterial activity. Stability, toxicity, corrosiveness and cleaning properties should be assessed before use. It is essential to monitor their effectiveness, i.e., by regular “in-use” tests under actual conditions of use on the wards/units.

3. The main problem in choosing the wrong disinfectant or using them incorrectly is that they may allow the survival and multiplication of bacteria. These bacteria then spread by spillage, as aerosols, or by being carried over on mops or other equipment that is being supposedly disinfected.

Guide to the Use of Disinfectants*

The following should be adhered to:

1. Follow manufacturer’s instructions AND ensure that the correct (optimum) dilution is used.

2. Check expiry date of the solution. The date should be clearly marked on the container.

3. Disinfectant containers must be thoroughly cleaned or sterilized before refill between uses. NEVER TOP UP!!.

4. Disinfectants must not be used to sterilize instruments or equipment (unless specified in the disinfectant policy, e.g. endoscopes).

5. Disinfectants should be supplied, preferably ready for use from the pharmacy (new stocks to be supplied on receipt of empty containers). Do not discard empty containers or use them to store other solutions. Chemicals can be harmful when used in the wrong situations.

6. Open containers of disinfectant should not be tolerated in any health care facility environment. There is a serious risk of contamination with multiple antibiotic-resistant bacteria such as Pseudomonas spp and spores.

7. Where disinfectants are indicated for use on surfaces, WIPE! Do not wash, bathe or flood-wash.

8. Always thoroughly decontaminate, then clean articles before disinfection, i.e., remove any substance such as dirt and biological materials.
9. The health care facility pharmacy should ensure that:

- The containers are thoroughly cleaned, washed and dried.
- The containers are clearly labelled with the type of contents, the in-use dilution and the expiry date.
- None of the disinfectants are exposed to inactivating substances, i.e. cork, rubber caps or incompatible detergents.

10. The disinfectants are diluted by knowledgeable personnel in manageable quantities, e.g. 5 litres or less. This will reduce waste and that partially filled containers will not be left on the wards (prevent hoarding)*.

Calculation of Concentrations

- Many active chlorine compounds are available at various strengths; however, the most widely used for chemical disinfection is sodium hypochlorite. Household bleach or laundry bleach is a solution of 5.25% or 52,500 parts per million (ppm) of sodium hypochlorite.

- Note that a 10% or 1:10 dilution of bleach will result in a 0.525% or 5250 ppm solution of chlorine. Rounded off, 0.5% is 5,000 ppm solution of chlorine.

- Thus, 100 ppm available chlorine means 100 out of every million parts of chlorine in the solution are available to produce a disinfectant effect.

- The following calculations are included to assist in the preparation of chlorine solutions (see Tables 9-10A).

1. **Preparing a Dilute Chlorine Solution***

**Using Liquid Bleach**

*Example I*

Chlorine in liquid bleach comes in different concentrations. Any concentration can be used to make a dilute chlorine solution by applying the following formula:

\[
\left( \frac{\text{\% chlorine in liquid bleach}}{\text{\% chlorine desired}} \right) - 1 = \text{Total parts of water for each part bleach}^{\dagger}
\]

*Example:* To make a 0.5\% chlorine solution from 3.5\%‡ bleach:

\[
\left[ \frac{3.5\%}{0.5\%} \right] - 1 = [7] - = 6 \text{ parts water for each part bleach}
\]

Therefore, you must add 1 part bleach to 6 parts water to make a 0.5\% chlorine solution.

\(^{\dagger}\) “Parts” can be used for any unit of measure (e.g. ounce, litre or gallon) or any container used for measuring, such as a pitcher.

\(^{\ddagger}\) In countries where French products are available, the amount of active chlorine is usually expressed in degrees chlorum. One degree chlorum is equivalent to 0.3\% active chlorine.

**Using Bleach Powder**

If using bleach powder, \(^{\dagger}\) calculate the ratio of bleach to water by using the following formula:

\[
\left( \frac{\text{\% chlorine desired}}{\text{\% chlorine in bleach powder}} \right) \times 1,000 = \text{Number of grams of powder for each litre of water}
\]

*Example:* To make a 0.5\% chlorine solution from calcium hypochlorite powder containing 35\% active chlorine:

\[
\left( \frac{0.5\%}{35\%} \right) \times 1,000 = 0.0143 \times 1,000 = 14.3
\]

Therefore, you must dissolve 14.3 grams of calcium hypochlorite powder in each litre of water used to make a 0.5\% chlorine solution.

\(^{\dagger}\) When bleach powder is used; the resulting chlorine solution is likely to be cloudy (milky).

**Example II**

**Formula for Making a Dilute Solution from a Concentrated Solution**

\[ \text{Total Parts (TP) (H2O)} = \left[ \frac{\% \text{ Concentrate}}{\% \text{ Dilute}} \right] - 1 \]

**Example:** To make a dilute solution (0.1%) from 5% concentrated solution.

1. Calculate TP (H2O) = \[ \frac{5.0\%}{0.1\%} \] - 1 = 50 - 1 = 49

2. Take 1 part concentrated solution and add to 49 parts boiled (filtered if necessary) water.

**Formula for Making a Chlorine-Releasing Solution from a Dry Powder**

\[ \text{Grams/Liter} = \left[ \frac{\% \text{ Dilute}}{\% \text{ Concentrate}} \right] \times 1000 \]

**Example:** To make a dilute chlorine-releasing solution (0.5%) from a concentrated powder (35%).

1. Calculate Grams/litre = \[ \frac{0.5\%}{35\%} \] \times 1000 = 14.2 g/l

2. Add 14.2 grams (approximately 14 g) to 1 litre of water.

Source: *Infection Prevention.* [http://www.reproline.jhu.edu/english/6read/6multi/pg/ip2.htm](http://www.reproline.jhu.edu/english/6read/6multi/pg/ip2.htm)
**Example III**

Undissociated hypochlorite is antibacterial. Amounts or concentration of hypochlorite = free or active or available chlorine*

To calculate parts per million (ppm) using CLOROX as an example:

CLOROX has 5.2% available sodium hypochlorite (find on label of chlorine solution to be used)

5.25% available hypochlorite =
- 5.25 grams hypochlorite per 100 millilitres
- 52.5 grams hypochlorite per litre
- 52500 milligrams hypochlorite per litre
- 52500 ppm of hypochlorite.

One gallon CLOROX = 52500 ppm of hypochlorite
for 100 ppm chlorine solution = 52500 ÷ 100 = dilution factor of 1:525
i.e. 1 gallon of CLOROX in 525 gallons of water = 100 ppm chlorine solution.
for 200 ppm chlorine solution = 52500 ÷ 200 = dilution factor of 1:262.5
i.e. 1 gallon of CLOROX in 262.5 gallons of water = 200 ppm chlorine solution.

\[ x = 0.0095 \text{ gallons of CLOROX in 10 gallons of water} = 50 \text{ ppm chlorine solution.} \]

3750 millilitres = 1 gallon
3750 millilitres x 0.0095 gallons of CLOROX = 35.7 millilitres in 10 gallons of water = 50 ppm chlorine solution.
30 millilitres = 1 fluid ounce.
35.7 millilitres ÷ 30 millilitres = 1.19 fluid ounce

1.2 fl oz of CLOROX in 10 gallons of water = 50 ppm chlorine solution.
2.4 fl oz of CLOROX in 10 gallons of water = 100 ppm chlorine solution.
5.0 fl oz of CLOROX in 10 gallons of water = 200 ppm chlorine solution.

\[ 2 \text{ tablespoons} = 1 \text{ fl oz.} \]
\[ 5.0 \text{ fl oz of CLOROX in 10 gallons of water} = 200 \text{ ppm chlorine solution.} \]
\[ 0.5 \text{ fl oz of CLOROX in 1 gallon of water} = 200 \text{ ppm chlorine solution.} \]
\[ = 1 \text{ tablespoon per 1 gallon of water} = \text{CLOROX recommendation.} \]

**To change ppm to a percent**

\[ \text{(ppm desired ÷ 1,000,000) x 100} = \% \]

**To change % to ppm**

\[ (\% ÷ 100) \times 1,000,000 = \text{ppm} \]

*Source: [Standard Operating Procedures](http://aruba.nysaes.cornell.edu/fst/faculty/mclehan/apple/sopsansoln.html)*
2. **Using Chlorine-Releasing Tablets**

Follow the manufacturer’s instructions, since the percentage of active chlorine in these products varies. If the instructions are not available with the tablets received from central supply, ask for the product’s instruction sheet.

INTRODUCTION

Appropriate decontamination, cleaning, disinfection and sterilization of patient care equipment are important in limiting and/or preventing the transmission of micro-organisms related to reusable patient care equipment.

The reprocessing method required for a specific item will depend on the item’s intended use, risk of infection to the patient, and the amount of soiling.

Decontamination and cleaning are always essential prior to disinfection or sterilization. An item that has not been decontaminated and cleaned cannot be assuredly disinfected or sterilized.

The rationale for the methods of decontamination, cleaning, disinfection and/or sterilization process used for surgical instruments and equipment depends on many factors including the level of potential risk of infection to the patient.

The level of risks determines the reprocessing of surgical instruments and equipment. See Table 11.
### Table 11: Classification of Risks

<table>
<thead>
<tr>
<th>Class</th>
<th>Use</th>
<th>Instruments/Equipment</th>
<th>Reprocessing</th>
</tr>
</thead>
<tbody>
<tr>
<td>Critical/ High-risk</td>
<td>• Enters body cavities, tissues and vascular system, in contact with break in the skin or mucous membranes.</td>
<td>• Surgical instruments, needles, catheters (cardiac and urinary) and prosthetic implants, intra-uterine devices.</td>
<td>• Decontamination, cleaning followed by sterilization.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Equipment used on highly infectious patients.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Items contaminated with highly virulent microorganisms, e.g. haemorrhagic viruses, rabies virus.</td>
<td></td>
</tr>
<tr>
<td>Semi-Critical/ Intermediate-risk</td>
<td>• In contact with intact mucous membranes or non-intact skin.</td>
<td>• Endoscopes, respiratory equipment including laryngoscope and blade, endotracheal and tracheosotomy tubes, oropharyngeal and nasal airways, thermometers.</td>
<td>• Decontamination, cleaning followed by high-level disinfection.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Equipment used on patients susceptible to infection.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Linen, utensils used on patients infected with highly virulent and infectious pathogens, e.g. Hepatitis B, Mycobacterium tuberculosis, Shigella.</td>
<td></td>
</tr>
<tr>
<td>Non-Critical/ Low-risk</td>
<td>• In contact with intact skin.</td>
<td>• Stethoscopes, blood pressure apparatus, bedpans, urinals, washing bowls, utensils, toilets, linen.</td>
<td>• Decontamination, cleaning followed by low or intermediate-level disinfection.</td>
</tr>
<tr>
<td>Minimal risk</td>
<td>• Not in close contact with patient, or in close proximity but with low contamination risk.</td>
<td>• Walls, floors, sinks, bedframes, lockers.</td>
<td>• Cleaning with detergent and drying.</td>
</tr>
</tbody>
</table>
Risk Categories in the Environment

Units or areas within a unit should be classified into risk categories and catered for accordingly (see Section VIII: Housekeeping).

**High Risk Areas**
- Operating Theatre
- Labour and Delivery Rooms
- ICU
- Dressing Room
- Laboratories
- Dental Unit
- Neonatal Unit
- Isolation Room.

**Low Risk Areas**
- Pharmacy
- Physiotherapy
- X-ray Department
- Offices
- Kitchen.

**THE STEPS OF PROCESSING**

Proper processing involves several steps that reduce the risk of transmitting infections from used instruments and other items to health care workers and patients. For proper processing, it is essential to perform the steps in the correct order. **Figure 26** outlines the steps in processing.

![Figure 26: Processing](image-url)

Step 1. **Decontamination**

Decontamination is the first step in reprocessing instruments and other items for reuse. It makes soiled instruments and other items safe to handle by health care workers before cleaning.

**Decontamination Procedure**

- Decontamination is done **before** leaving the treatment or procedure room.

- **Immediately after** a procedure and **before** the removal of gloves, place items in 0.5% chlorine solution.

- Allow to soak for 10 minutes. This step rapidly inactivates HBV and HIV.

- Dip gloved hands in the chlorine solution before removing the gloves. Remove gloves by inverting them.

- Deposit gloves into the hazardous waste container for disposal.

- After 10 minutes of soaking in 0.5% chlorine solution remove instruments. Do not soak more than 10 minutes.

- Rinse immediately or place instruments immediately in soapy water for cleaning.
Step 2. Cleaning of Instruments and Equipment

Cleaning instruments and equipment is the next important step in processing and refers to scrubbing items with a brush, detergent, and water to remove blood, other body fluids, organic material, tissue and dirt. In addition, cleaning greatly reduces the number of micro-organisms (including bacterial endospores) on items and is a crucial step in processing. If items have not first been cleaned, further processing might not be effective because:

- Micro-organisms trapped in organic material may be protected and survive further processing.
- Organic material and dirt can make the chemicals used in some processing techniques less effective.

Cleaning Procedure

- Cleaning that follows decontamination can remove up to 90% of micro-organisms (bacteria, viruses, fungi and parasites) and is the best way to reduce the number of endospores, which cause tetanus and gangrene.
- Neither sterilization nor high-level disinfection procedures are effective without prior decontamination and cleaning using detergent, water and brushes.
- Cleaning should be done under the surface of the water, using liquid soap and friction to remove all organic material from instruments.
- After cleaning, rinse items in clean water until no detergent remains.
- Air-dry items whenever possible.
- Use heavy-duty gloves for cleaning instruments.
- Wash hands after removing gloves.
Care of All Instruments

- Those with moving parts should be lubricated after drying.
- Avoid oils that may protect bacteria during autoclaving; a water soluble lubricant is recommended.
- Never use steel wool or abrasive powders on stainless steel instruments. Their use may seriously damage the corrosion resistant film of the instrument.
- Never label surgical instruments by impact marking. Striking any hardened instruments can cause stress and severe damage may result at a later date.
- Staining and spotting can be caused by condensation of water droplets on the surface, leaving slight mineral deposits.
- General dullness of the surface finish may arise from water softening systems.
- When instruments do stain in spite of all good care taken they can be cleaned by using a commercially available rust and stain remover.

New Instruments

- All new instruments are supplied without lubrication. It is recommended that all be carefully washed and dried and any moving part lubricated.
- Whenever cleaning, regardless of method, keep ratchets unlocked and box joints open.
- When instruments are no longer new, avoid as far a possible contact between stainless steel instruments and any of the following substances: barium chloride, aluminium chloride, bromide and iodine containing compounds.

Manual Cleaning of Soiled Instruments and Equipment

- Routine cleaning of soiled instruments is done immediately after the procedure.
- When an operation is in progress do not drop instruments into a holding solution of disinfectant. If the instruments are not cleaned first, disinfectants such as glutaraldehyde or alcohol act as fixatives of any organic material present, making it difficult to remove.
- Instruments should not be soaked in saline, as they will become pitted.
- Dilute detergent properly as per supplier’s direction.
- Completely dismantle all items and leave instruments open.
Use warm water, detergent and hard brush to completely remove the blood, tissue, food and other residue, paying special attention to small teeth of instruments and joints.

Finally rinse with clean water to remove traces of detergent.

Dry properly. Failure to remove water from trapped areas will cause corrosion.

For sterilization wrap the instruments properly to prevent contact corrosion.

1. There is no substitute for proper cleaning. Whether steam sterilization, ethylene oxide or disinfectants are used they cannot penetrate debris. These processes will not work when instruments are not cleaned properly.

2. Always keep soiled items separated from clean and disinfected/sterile areas to prevent cross contamination.

3. Consider the item contaminated when packaging is torn, damaged, wet, dropped on the floor and when the expiry date has passed.

4. Never let a clean item stand in liquid. DRY! Keep all instruments open.
Step 3. **High-level Disinfection (HLD)**

HLD is the process that eliminates all microorganisms (including bacteria, viruses, fungi and parasites), but does **not** reliably kill all bacterial endospores, which cause diseases such as tetanus and gas gangrene. HLD is suitable for instruments and items that come in contact with broken skin or intact mucous membranes.

Because sterilization kills **all** microorganisms, including bacterial endospores, it is preferable to HLD for instruments and other items that will come in contact with the bloodstream or tissues under the skin. If sterilization is not available, HLD is the **only** acceptable alternative.

HLD can be performed by: Boiling; Soaking in Chemicals, Steaming.

**A. HLD by Boiling**

**Step 1**

- Decontaminate and clean all items to be boiled.
- Open all hinged items and disassemble those with sliding or multiple parts.
- Completely submerge all items in the water in the pot or boiler.
- Place any bowls and containers upright, not upside-down, and fill with water.

**Step 2**

- Cover the pot or close the lid on the boiler and bring the water to a gentle, rolling boil.

**Step 3**

- When the water comes to a rolling boil, start timing for 20 minutes. Use a timer to make sure to record the time that boiling begins. From this point on, do not add or remove any water and do not add any items to the pot or boiler.

**Step 4**

- Lower the heat to keep the water at a gentle, rolling boil.
Section VII: Disinfection and Sterilization

If the water boils too vigorously, it will evaporate, and the items may become damaged if they bounce around the container and hit the sidewalls and other items being boiled. Lower heat also saves fuel or electricity.

Step 5

- After 20 minutes, remove the items using dry, HLD pickups (lifters, cheatle forceps). Place the items on an HLD tray or in an HLD container away from insects and dust.

An HLD tray or container can be prepared by boiling it for 20 minutes or by filling it with a 0.5% chlorine solution and letting it soak for 20 minutes, then draining the chlorine solution and rinsing thoroughly with sterile water.

Step 6

- Allow to air-dry before use or storage.

Step 7

- Use items immediately or keep them in a covered, sterile or HLD container for up to one week.

Never leave boiled items in water that has stopped boiling; they can become contaminated as the water cools down.

Tips for HLD by Boiling

- Items must be completely covered with water. Open all hinged instruments and disassemble items with sliding or multiple parts.
- Always boil for 20 minutes. Start timing when the water reaches a rolling boil. If you forget to start timing the procedure, start timing at the point at which you realize this.
- Do not add anything to or remove anything from the boiler once boiling begins.
B. **HLD by Chemicals**

**Step 1**
- Decontaminate, clean, and thoroughly dry all instruments and other items to be processed. Water from wet items will dilute the chemical solution, thereby reducing its effectiveness.

**Step 2**
- **When using a glutaraldehyde solution:** Prepare the solution according to the manufacturer’s instructions. Ideally, an indicator strip should be used each time the solution is used to determine if the solution is still effective. After preparing the solution, place in a clean container with a lid. Mark the container with the date the solution was prepared and the date it expires.

- **When using a chlorine solution:** Prepare the 0.5% chlorine solution as described. Fresh solution should be made each day, or more often if the solution becomes cloudy. Put the solution in a clean container with a lid.

**Step 3**
- Open all hinged items and disassemble those with sliding or multiple parts. The solution must contact all surfaces in order for HLD to be achieved. Completely submerge all items in the solution. All parts of the items should be under the surface of the solution. Place any bowls and containers upright, not upside-down, and fill with the solution.

**Step 4**
- Cover the container, and allow the items to soak for 20 minutes. Do not add or remove any instruments or other items once timing has begun.

**Step 5**
- Remove the items from the solution using dry, HLD pickups (lifters, cheatle forceps).

**Step 6**
- Rinse thoroughly with sterile water to remove the residue that chemical sterilants leave on items. This residue is toxic to skin and tissue.
**Step 7**

- Place the items on an HLD tray or in an HLD container and allow to air-dry before use or storage. Use items immediately or keep in a covered, dry HLD container and use within one week.

*An HLD tray or container can be prepared by boiling it for 20 minutes or by filling it with a 0.5% chlorine solution and letting it soak for 20 minutes, then draining the chlorine solution and rinsing thoroughly with boiled water.*

---

**Tips for Chemical HLD**

- Items must be completely covered with solution.
- Open all hinged instruments and disassemble items with sliding or multiple parts.
- Soak for 20 minutes. If you forget to start timing, start at the point at which you remember.
- Do not add or remove anything once timing begins.
- Rinse items thoroughly with boiled water.

Antiseptics should **never** be used for HLD.
Desirable Properties of Chemical Disinfectants

- Broad spectrum of activity
- Rapid activity
- Stable when in contact with organic matter, soaps, detergents, hard water, plastic, etc.
- Non-toxic
- Non-corrosive
- Non-damaging to equipment/substances treated
- Cost-effective and available.

Step 4: Sterilization

Sterilization protects patients by eliminating all micro-organisms (bacteria, viruses, fungi, and parasites), including bacterial endospores, from instruments and other items. Sterilization is recommended for instruments and other items that will come in contact with the bloodstream or tissues under the skin, as well as on draped and some surgical attire.

Sterilization can be performed using:

- High pressure steam (autoclaving)
- Dry heat (oven)
- Soaking in chemicals (cold sterilization)

**Heat** (autoclaving/steam and dry heat) is the most effective method of sterilization and reliable if monitored carefully. It is also cheaper than chemical methods. It should be considered first for all medical equipment that can withstand heat.

**Chemical** is the alternative where heat cannot be used, e.g. ethylene oxide and glutaraldehyde.
Sterilization by Heat

A. Dry Heat

<table>
<thead>
<tr>
<th>Time/Temperature</th>
<th>Temperature/Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 hour</td>
<td>170 degrees C (340 degrees F)</td>
</tr>
<tr>
<td>2 hours</td>
<td>160 degrees C (320 degrees F)</td>
</tr>
<tr>
<td>2½ hours</td>
<td>150 degrees C (300 degrees F)</td>
</tr>
<tr>
<td>3 hours</td>
<td>140 degrees C (285 degrees F)</td>
</tr>
</tbody>
</table>

B. Steam Heat

<table>
<thead>
<tr>
<th>Time</th>

</tr>
</thead>
<tbody>
<tr>
<td>20 minutes</td>
<td>121 degrees C (250 degrees F)</td>
</tr>
<tr>
<td></td>
<td>106 KPA (15 lbs/sq inch)</td>
</tr>
</tbody>
</table>

The units of pressure marked on an autoclave’s pressure gauge may vary from one autoclave to another.

C. Sterilization by Chemicals

Chemical sterilization method is used for instruments and other items that are heat-sensitive or when heat sterilization is not available.

Step 1

- Decontaminate, clean, and thoroughly dry all instruments and other items to be sterilized. Water from wet instruments and other items dilutes the chemical solution, thereby reducing its effectiveness.

Step 2

- Prepare the glutaraldehyde or other chemical solution by following the manufacturer’s instructions or use a solution that was prepared previously, as long as it is clear (not cloudy) and has not expired. After preparing the solution, put it in a clean container with a lid. Always mark the container with the date the solution was prepared and the date it expires.
**Section VII: Disinfection and Sterilization**

**Step 3**

- Open all hinged instruments and other items and disassemble those with sliding or multiple parts; the solution must contact all surfaces in order for sterilization to be achieved. Completely submerge all instruments and other items in the solution; all parts of the instruments and other items should be under the surface of the solution. Place any bowls and containers upright, not upside-down, and fill with the solution.

**Step 4**

- Follow the manufacturer’s instructions regarding the time necessary for sterilization to be achieved. In general, if the solution contains glutaraldehyde, cover the container, and allow the instruments and other items to soak for **8 to 10 hours**. Do not add or remove any instruments or other items once time has begun.

**Step 5**

- Remove the instruments and other items from the solution using large, sterile pickups (lifters, cheatle forceps).

**Step 6**

- Rinse thoroughly with **sterile** water to remove the residue that chemical sterilants leave on instruments and other items; this residue is toxic to skin and tissues.

> **Boiled water is not sterile; because boiling does not guarantee that bacterial endospores have been killed. Therefore, rinsing with boiled water can contaminate sterilized instruments and other items.**

**Step 7**

- Storage: Place the instruments and other items on a sterile tray or in a sterile container and allow to air-dry before use or storage. Use the instruments and other items immediately or keep in a covered, dry, sterile container and use within one week.
Step 5: Use or Storage

After processing, items should be used immediately or stored in such a way so that they do not become contaminated. Proper storage is as important as proper processing.

SUMMARY

It is important to perform the steps in the appropriate order for several reasons:

1. Decontamination should always be done first to make items safer to handle.
2. Cleaning should always be done before sterilization or HLD to remove material that can interfere with these processes.
3. Sterilization or HLD should be done before use or storage to minimize the risk of infections to patients during procedures. Table 12 summarizes the processing of instruments and equipment.
4. Items should be used or properly stored immediately after sterilization or HLD so that they do not become contaminated.

Sterilization is preferred over HLD for items that will come in contact with the bloodstream or tissues under the skin. In settings where tetanus is common, all attempts should be made to sterilize these items.

Sterilization or Disinfection – When to Choose

- The choice depends on the use of equipment or instruments (see Table 11 for definition of risk categories).
- Remember that heat is the preferred method of sterilization. Disinfectants are used only when the instruments or equipment cannot tolerate heat treatment, or disinfection only is required.
- Boiling “sterilizers” as used in the past do not sterilize and should be removed from health care facilities where “pressure type steam sterilizers” are available. If no sterilizer is present, disinfection is the procedure to use.

Decontaminating, cleaning, disinfecting, and sterilizing patient care equipment.

- All objects to be high-level disinfected or sterilized should first be thoroughly decontaminated and cleaned to remove all organic matter (e.g. blood, tissue) and other residue.

A. STERILIZATION*

Critical items that will enter tissue or vascular system or blood will flow through them.

*Procedure:

- Heat sterilization
- Chemisterilant
  - 2% glutaraldehyde
  - 6% hydrogen peroxide
  - 1% peracetic acid
  - 0.1% (1000 ppm) sodium hypochlorite

*Exposure time:* In hours, manufacturer’s recommendations.

B. HIGH-LEVEL DISINFECTANT (HLD)

Semi-critical items (except dental) that will come in contact with mucous membrane or non-intact skin.

*Procedure:

- HLD/Chemisterilant
  - 2% glutaraldehyde
  - 6% hydrogen peroxide
  - 1% peracetic acid
  - 0.1% (1000 ppm) sodium hypochlorite

*Exposure time:* 20 minutes
C. DISINFECTION

1. Intermediate-Level

   Semi-critical items and non-critical items.

   **Procedure:**  Disinfection

   - Sodium hypochlorite 0.1% (1000 ppm)
   - 70%-90% ethyl or isopropyl alcohol
   - Phenolic germicidal detergent solution
   - Iodophor germicidal detergent

   **Exposure time:**  10 minutes

2. Low-Level

   Non-critical items

   **Procedure:**  Disinfection

   - Ethyl or isopropyl alcohol 70%-90%
   - Sodium hypochlorite 0.01% (100 ppm)
   - Phenolic germicidal detergent solution
   - Iodophor germicidal detergent solution
   - Quaternary ammonium germicidal detergent

   **Exposure time:**  10 minutes.

D. RECOMMENDATIONS FROM CENTERS FOR DISEASE CONTROL (CDC)*

- Sodium hypochlorite solution (household bleach) prepared daily.

- Concentrations ranging from approximately 500 ppm (1:100 dilution) (0.05%) sodium hypochlorite to 5,000 ppm (1:10 dilution) (0.5%) of household bleach are effective depending on the amount of organic material, (e.g. blood, mucus) present on the surface to be cleaned.
